Biological Activity of Cachectin

- Presumed important for wasting in chronic disease, cachectin was secreted by macrophages in response to LPS.
- Defined by its ability to shut off the synthesis of adipocyte lipoprotein lipase, an enzyme needed for the uptake and storage of plasma triglycerides.

1983

Isolation of mouse cachectin

- Pressure dialysis of medium from ~500 10 cm plates of LPS-activated RAW 264.7 cells (early harvest)
- ConA sepharose chromatography
- Isoelectric focusing in a glycerol gradient
- Preparative native gel electrophoresis
- Preparative SDS gel electrophoresis
- Yielded microgram quantities of an apparently pure 17.5 kD protein with approximately 2% yield of initial biological activity (prior to denaturing gel electrophoresis).
- Cachectin comprised 1-2% of the protein secreted by RAW 264.7 cells during the first two hours following LPS activation.

1984

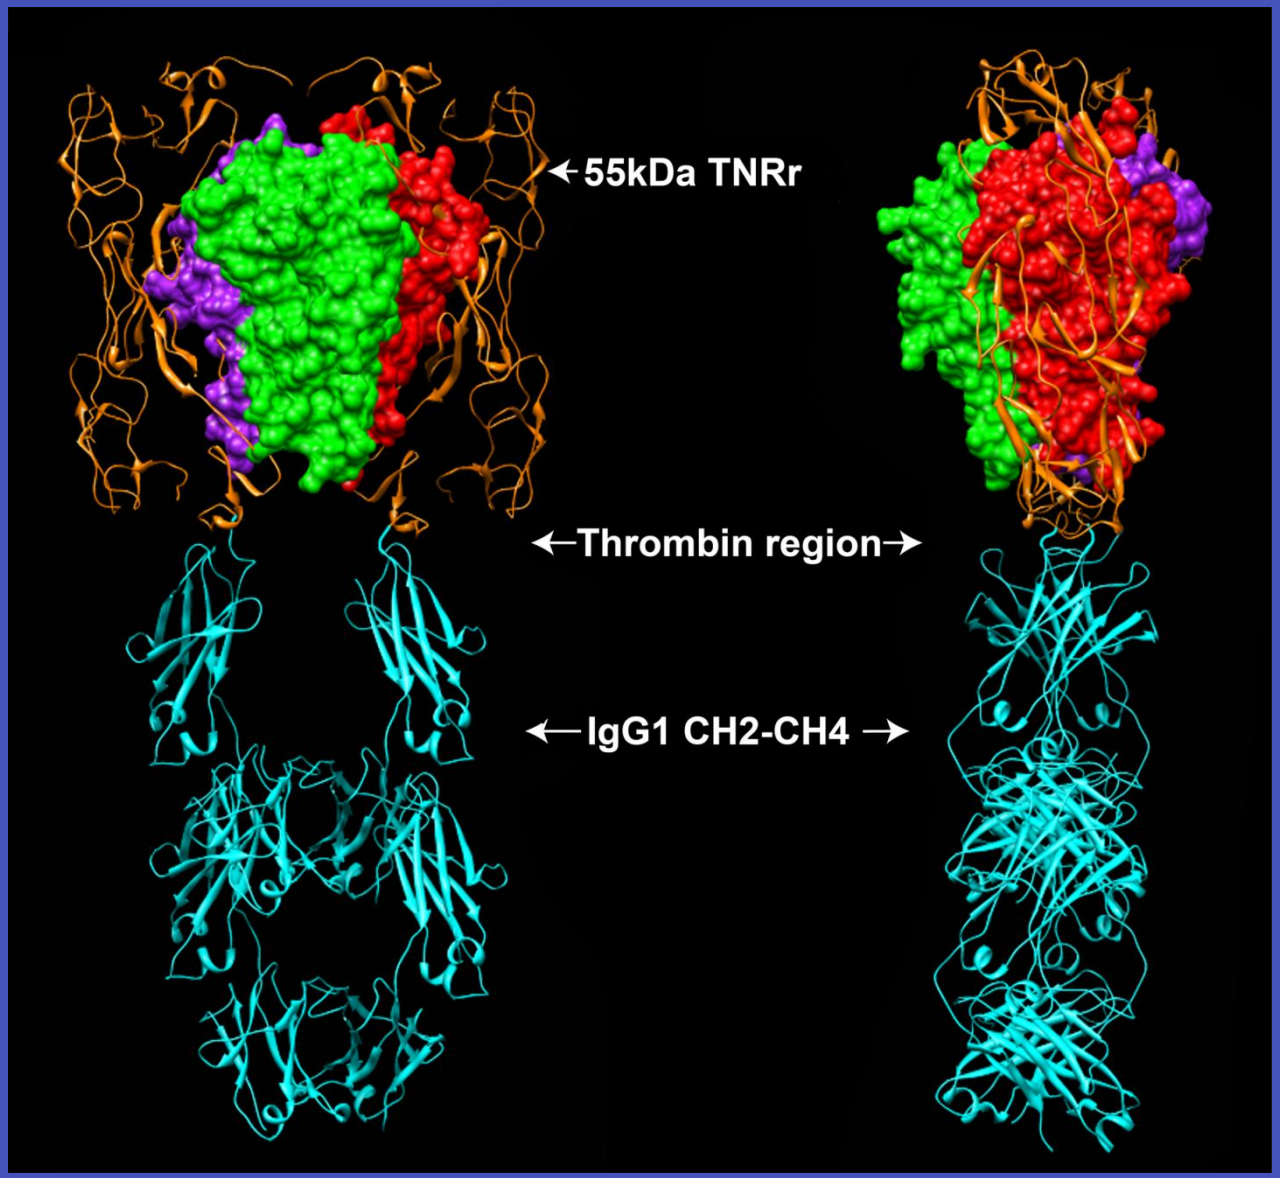
Looking at a model of a recombinant TNF inhibitor

1991

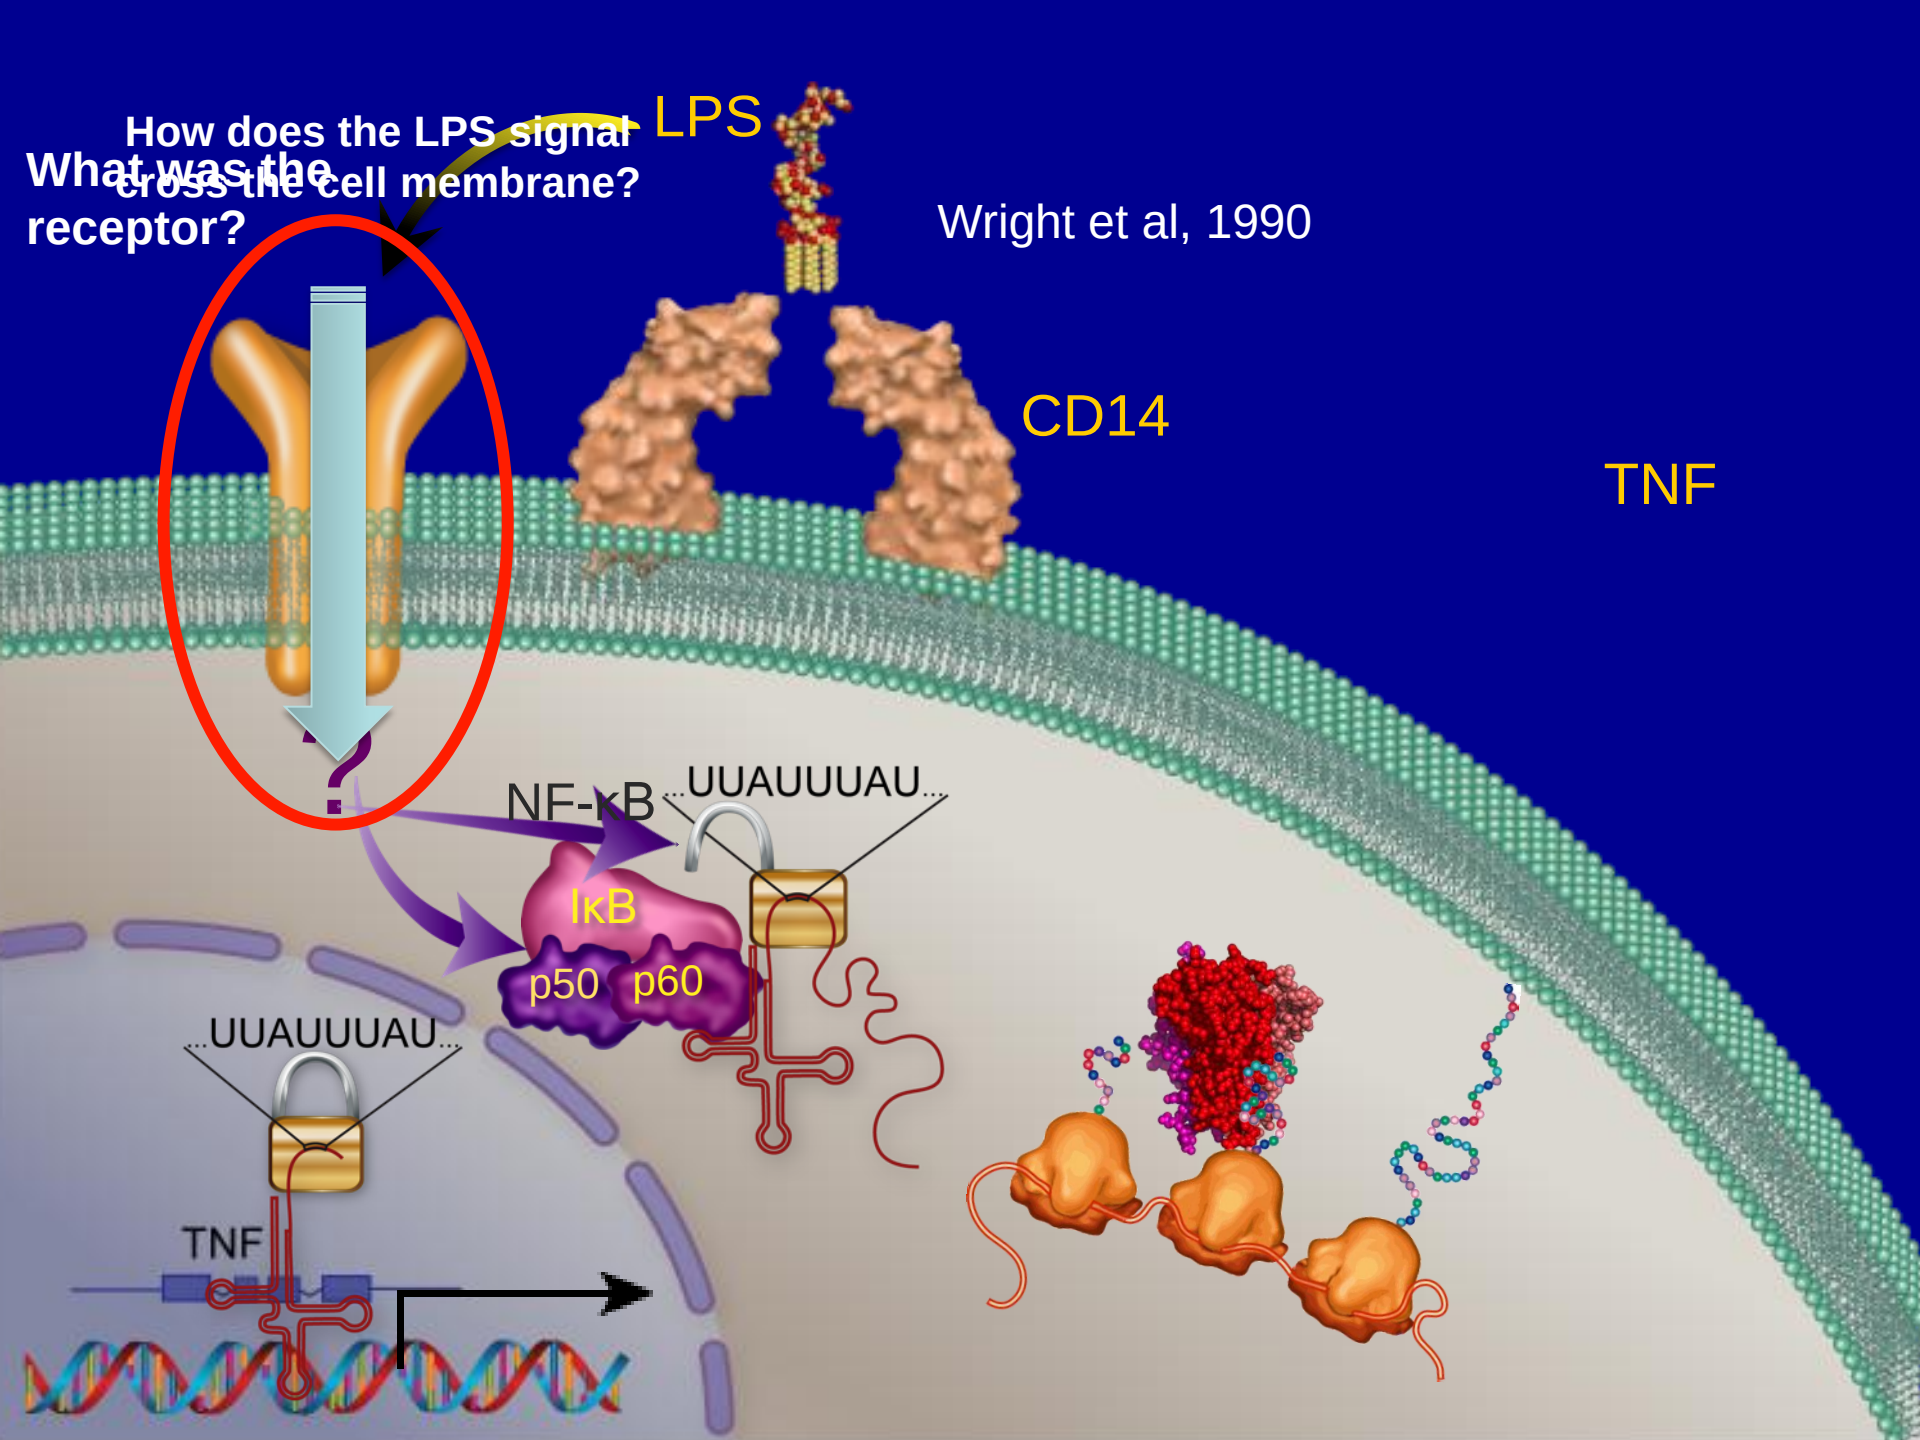


UT SOUTHWESTERN MEDICAL CENTER

Peppel et al, *JEM:* 174(6):1483-9, 1991

All the while, I wondered about how LPS was perceived by cells and gradually came to see this as the most important question in the field of immunity and inflammation.

- We still did not know how innate immune recognition worked, and this seemed an excellent entry point into that question.
- To this day, we don't know what drives sterile inflammation. Here too, I thought we might find molecules of primary importance in this class of diseases (RA, ankylosing spondylitis, others).



How does the LPS signal cross the cell membrane?
What was the receptor?

TNF

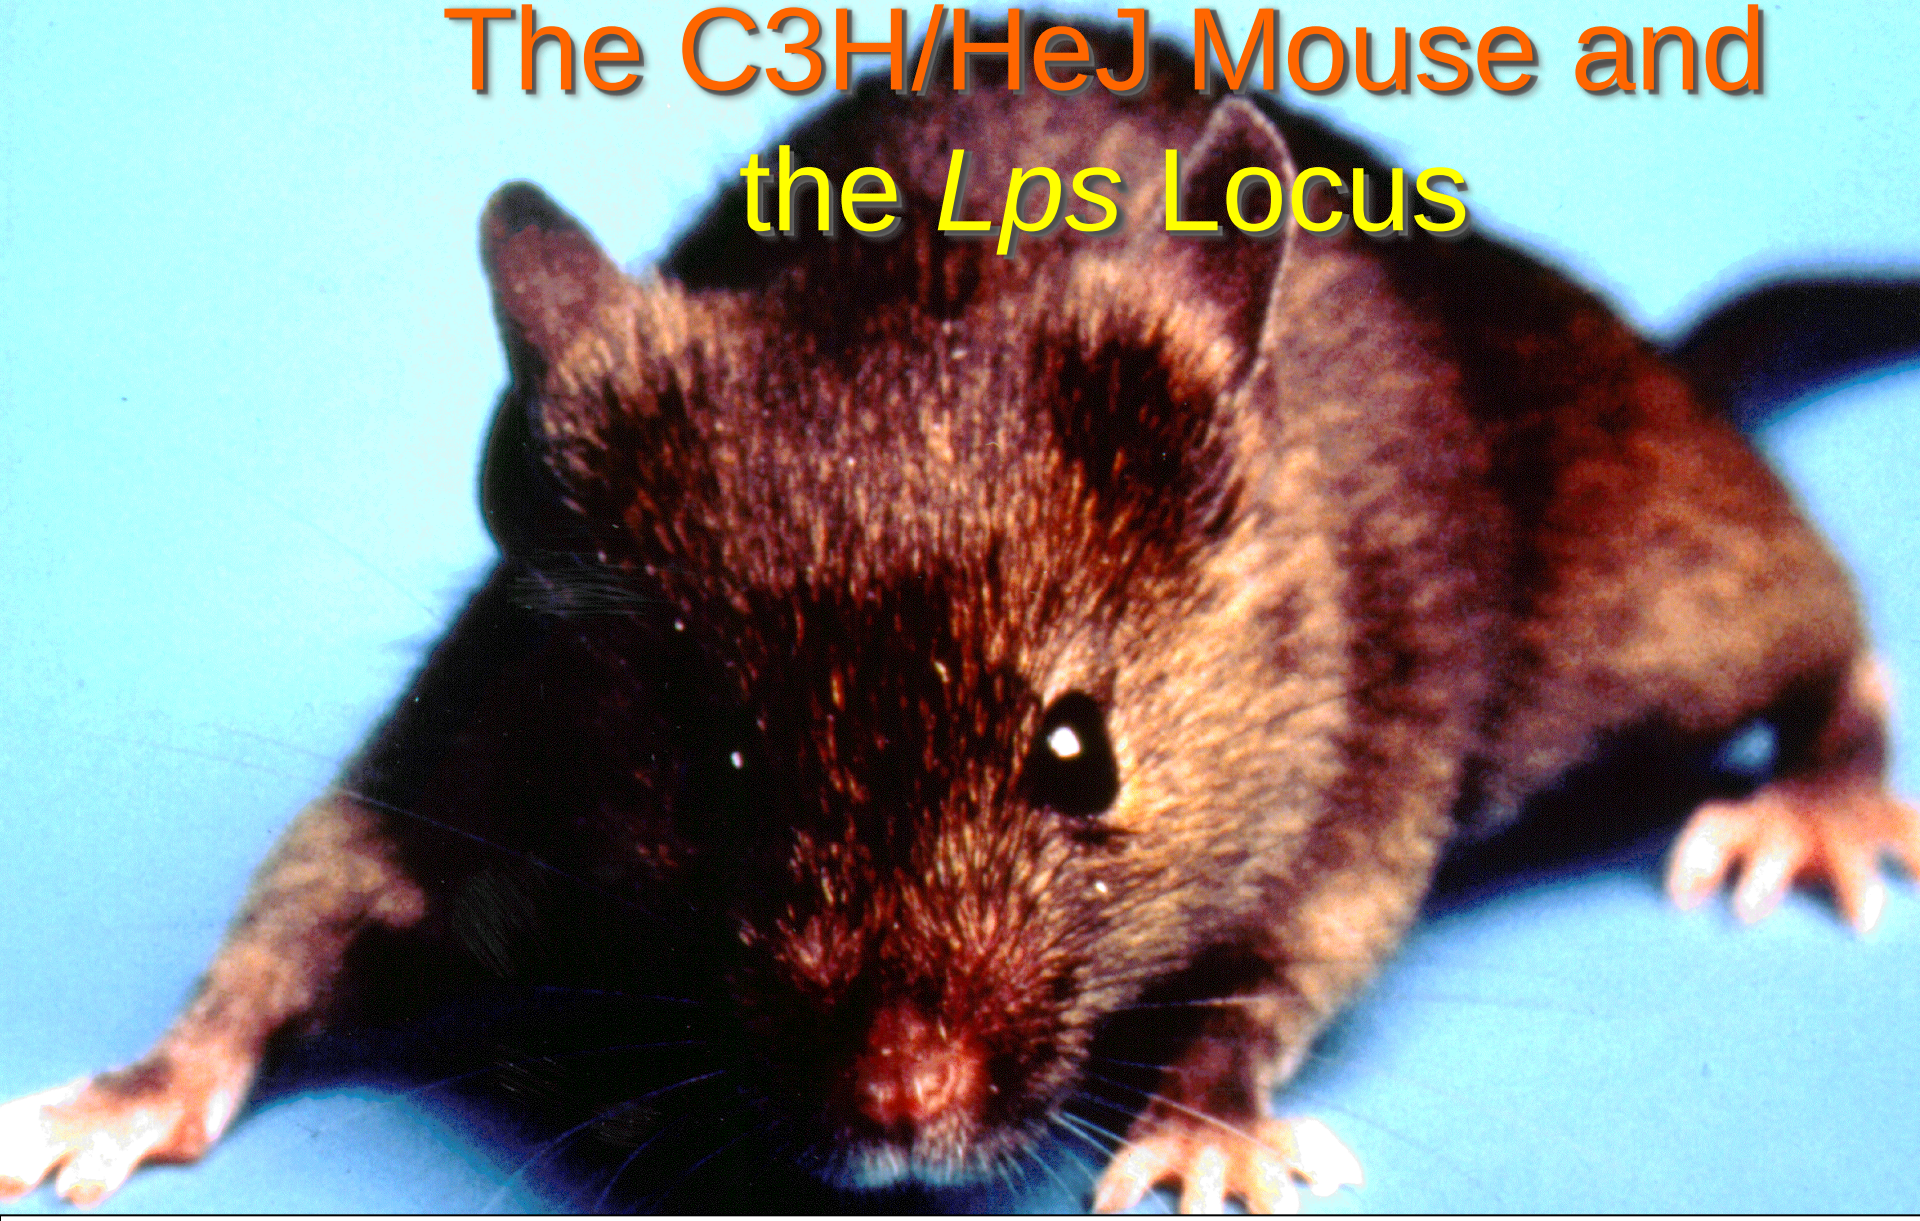
We made several attempts to find the LPS receptor using immunological methods, protein chemistry, and expression cDNA cloning. All these approaches were unsuccessful.

The LPS receptor was ultimately found using a pure genetic approach, based on two unrelated substrains of mice that couldn't respond to LPS.

The C3H/HeJ Mouse and the *Lps* Locus



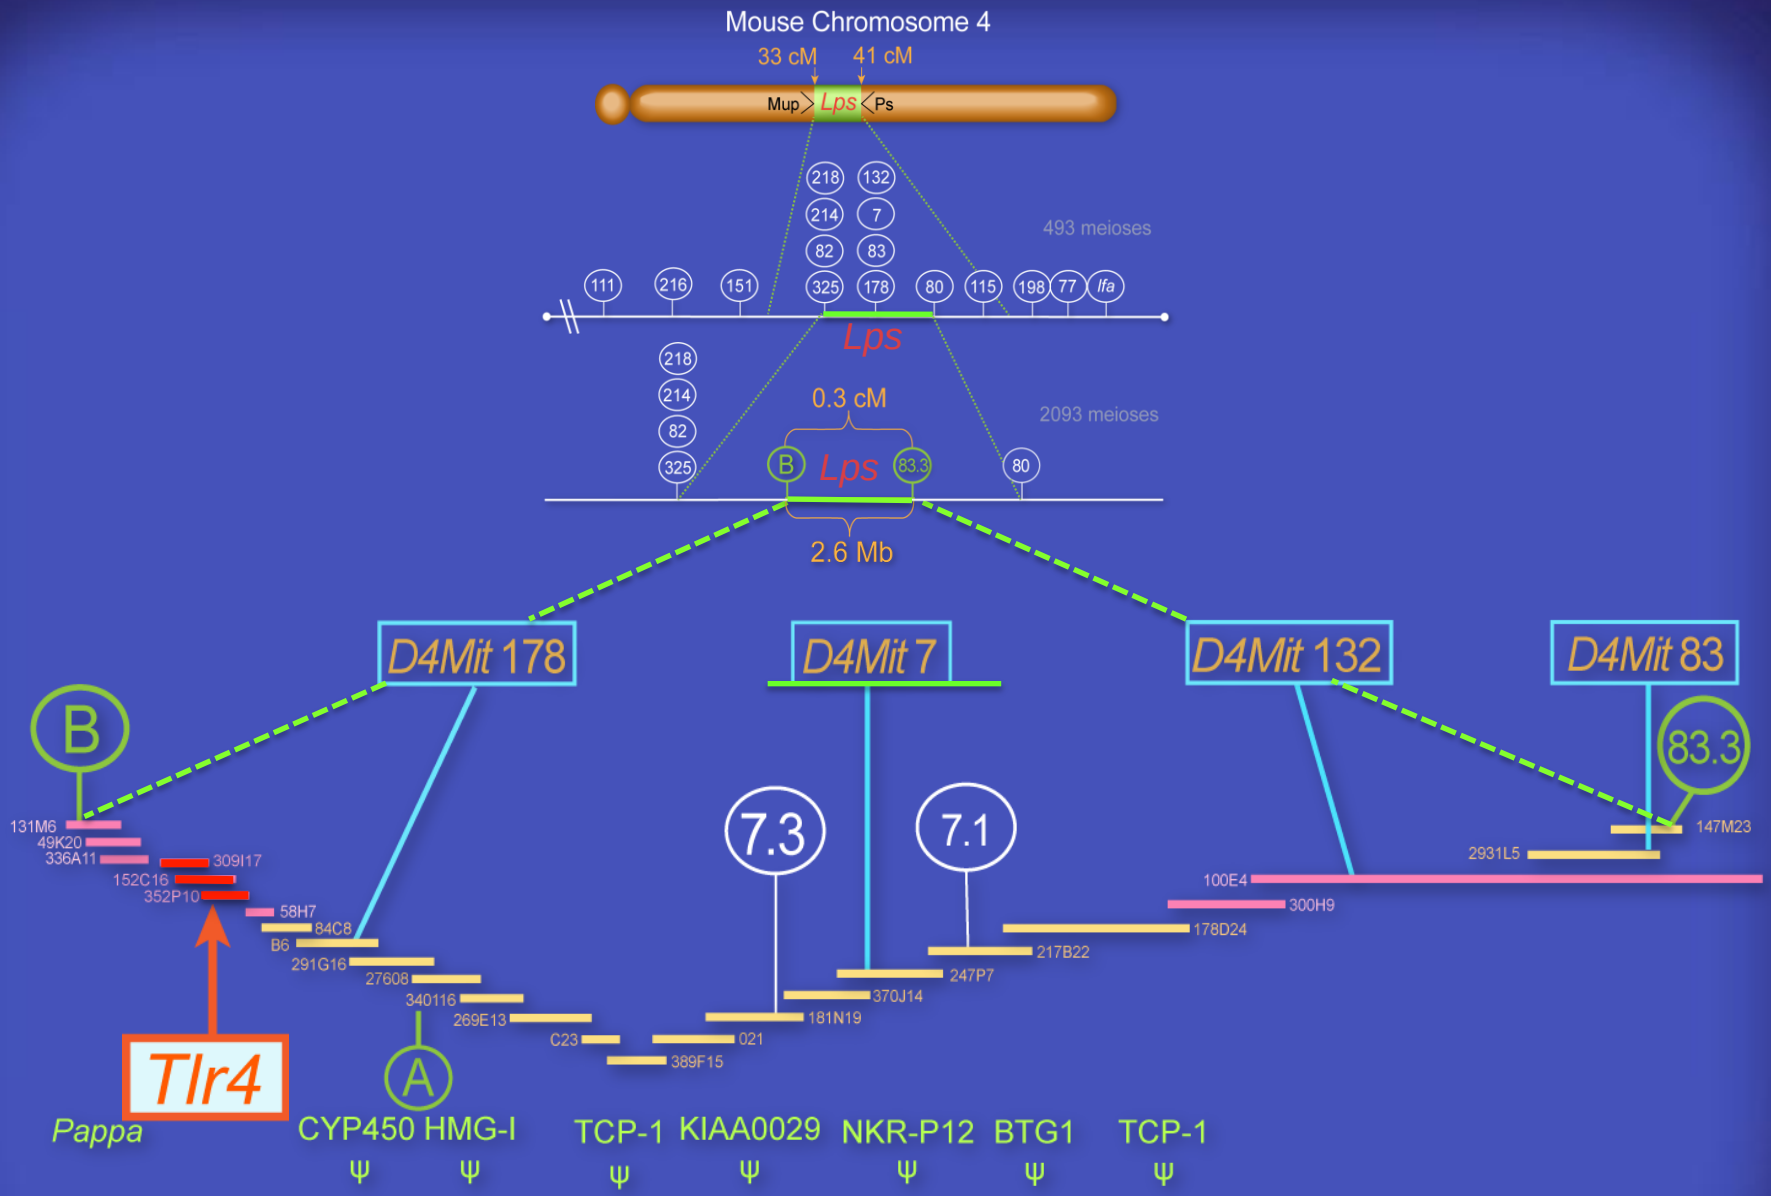
- Resistant to LPS (Heppner and Weiss, 1965), but highly susceptible to Salmonella (O'Brien, 1980)

The C57BL/10ScCr Mouse and the *Lps* Locus

- The same gene was affected in the LPS-refractory C57BL/10ScCr strain (Coutinho and Meo,1978).
- Located on Chr 4 (Watson and Riblet, 1978)

Beginning in 1993, we turned to positional cloning to try to find which gene was affected.

- Positional cloning = cloning by phenotype.
- One first establishes a “critical region,” delimited by markers in the genome, from which the phenotype emanates (genetic mapping)
- One then clones all the genomic DNA across the critical region, and identifies all the genes residing within it (physical mapping)
- Finally, one finds the causative mutation by comparing sequences of affected and control strains.



By summer of 1998, more than 90% of the critical region had been explored.

1998

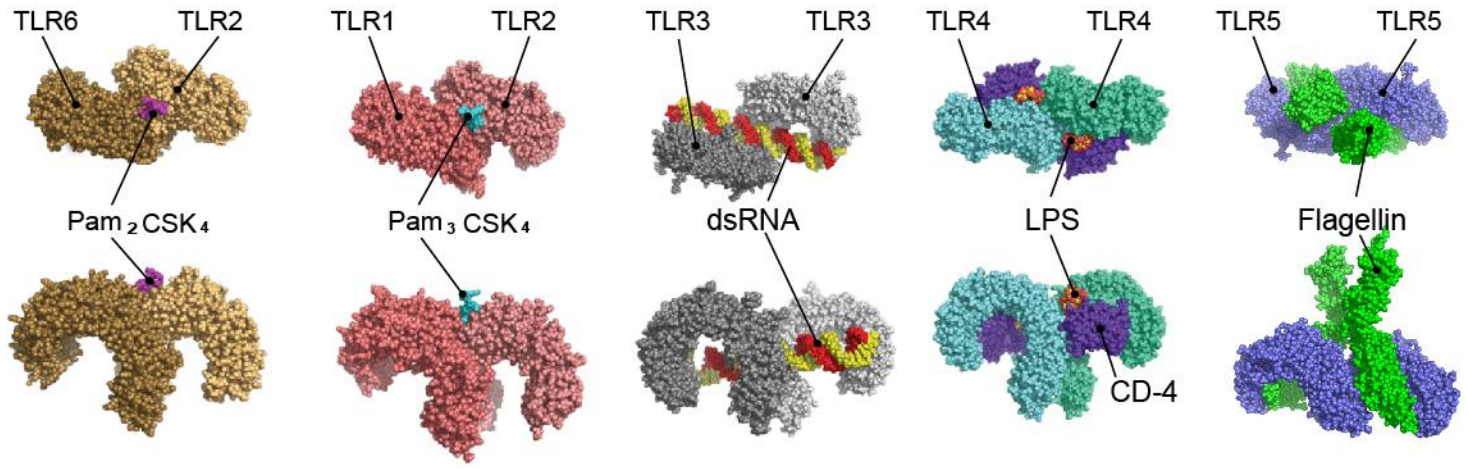
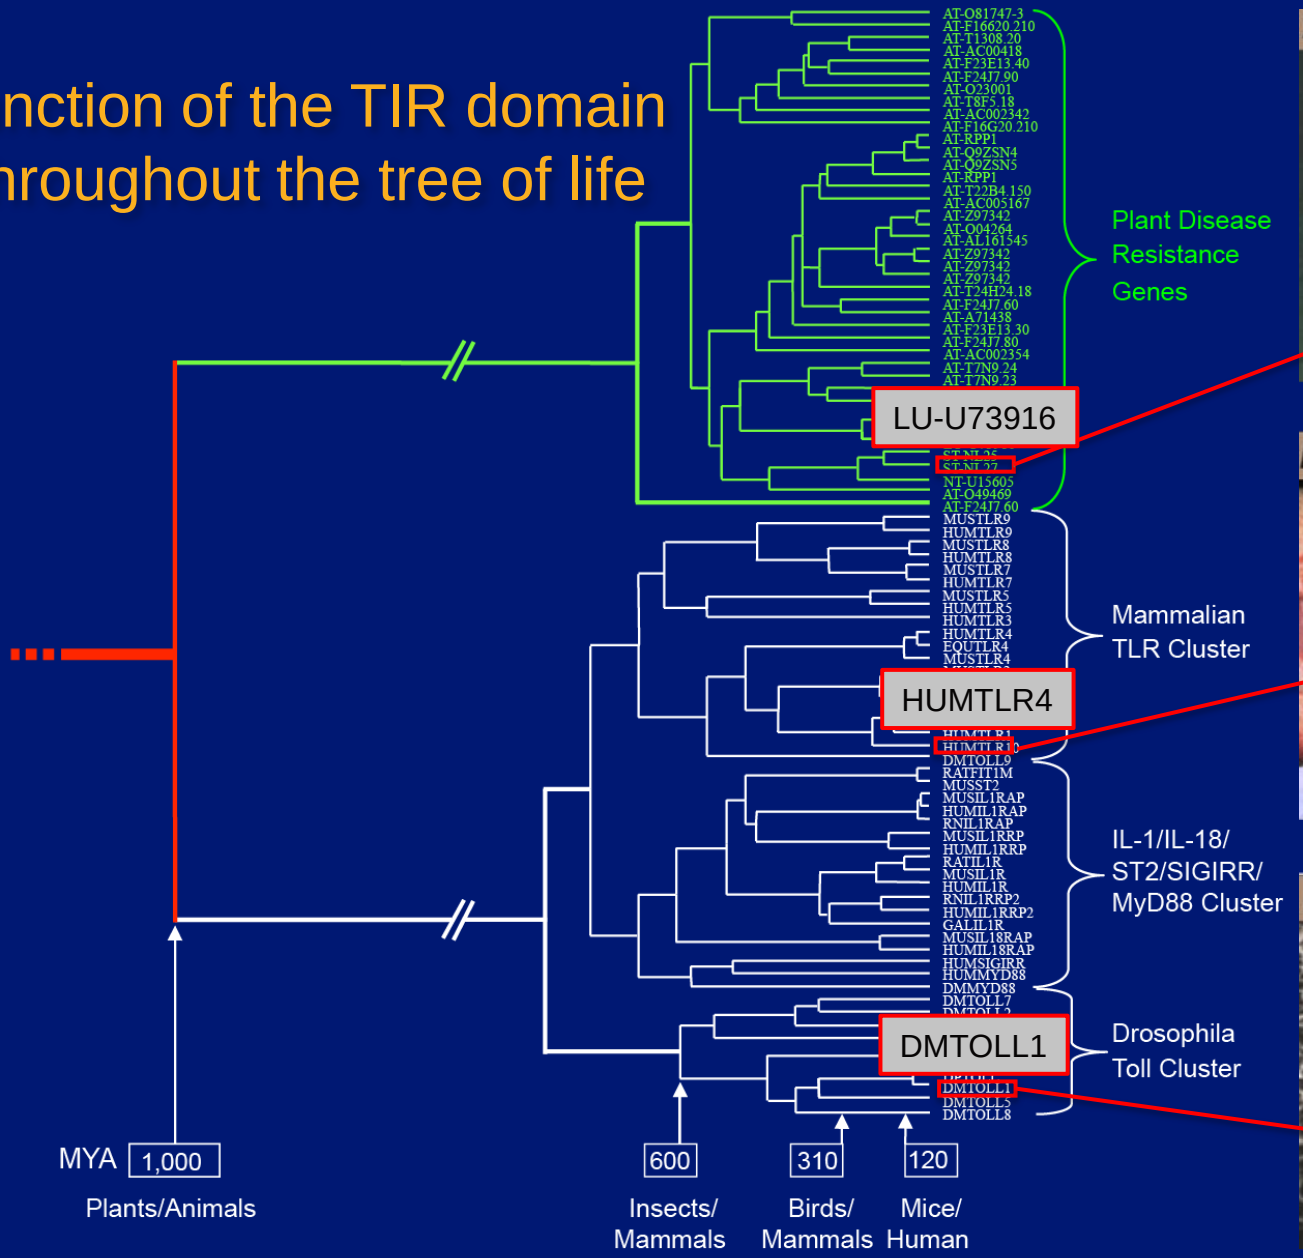
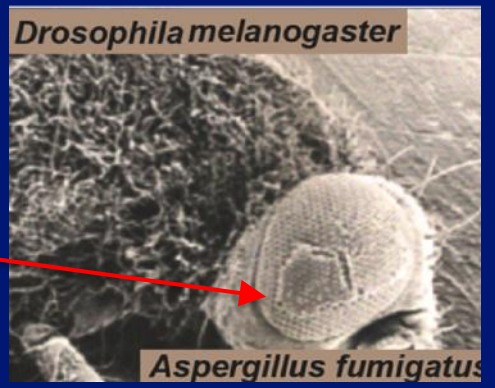
Crystal structure of the TLR4/MD-2/Lipid-A complex was published by Jie-Oh Lee (Park et al) in 2009

Now, the mode of binding of several ligands to TLRs is understood



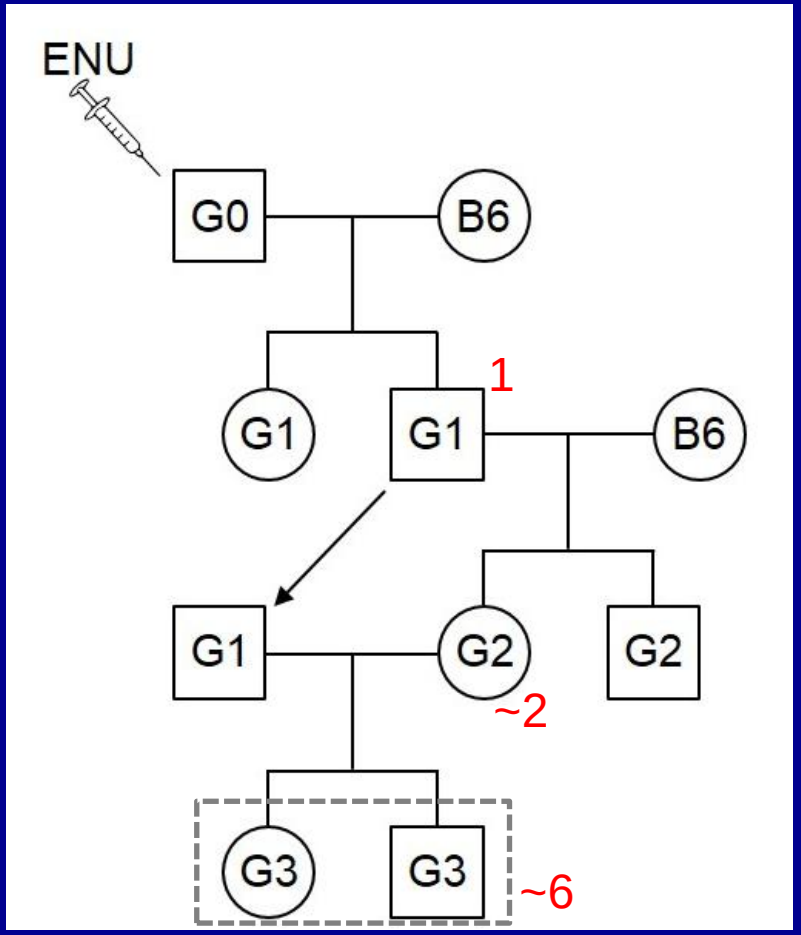
Receptor	TLR 1/2 or 2/6	TLR3	TLR4	TLR5	TLR7	TLR9
Ligands	Lipoproteins	Poly I:C, dsRNA	LPS	Flagellin	ssRNA	CpG-DNA
Source	Gram pos bacteria, fungi	Viruses	Gram neg bacteria	Bacterial flagellum	Viruses	Bacteria
Examples						
Function of the TIR domain throughout the tree of life

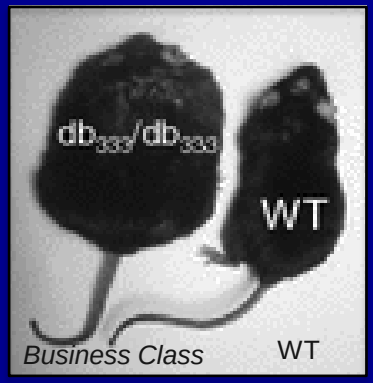




- The next set of questions had to do with the signaling pathway utilized by TLR4.
- There were no other spontaneous mutations in mice that could inform us of how LPS signaling worked.
- We decided to create new phenotypes using a mutagen (work that began in 2000).
- Many other aspects of immunity interested us as well, and these too were placed under surveillance in screens for phenovariance.

Making new phenotypes in mice to understand TLR signaling: mutagenesis with ENU

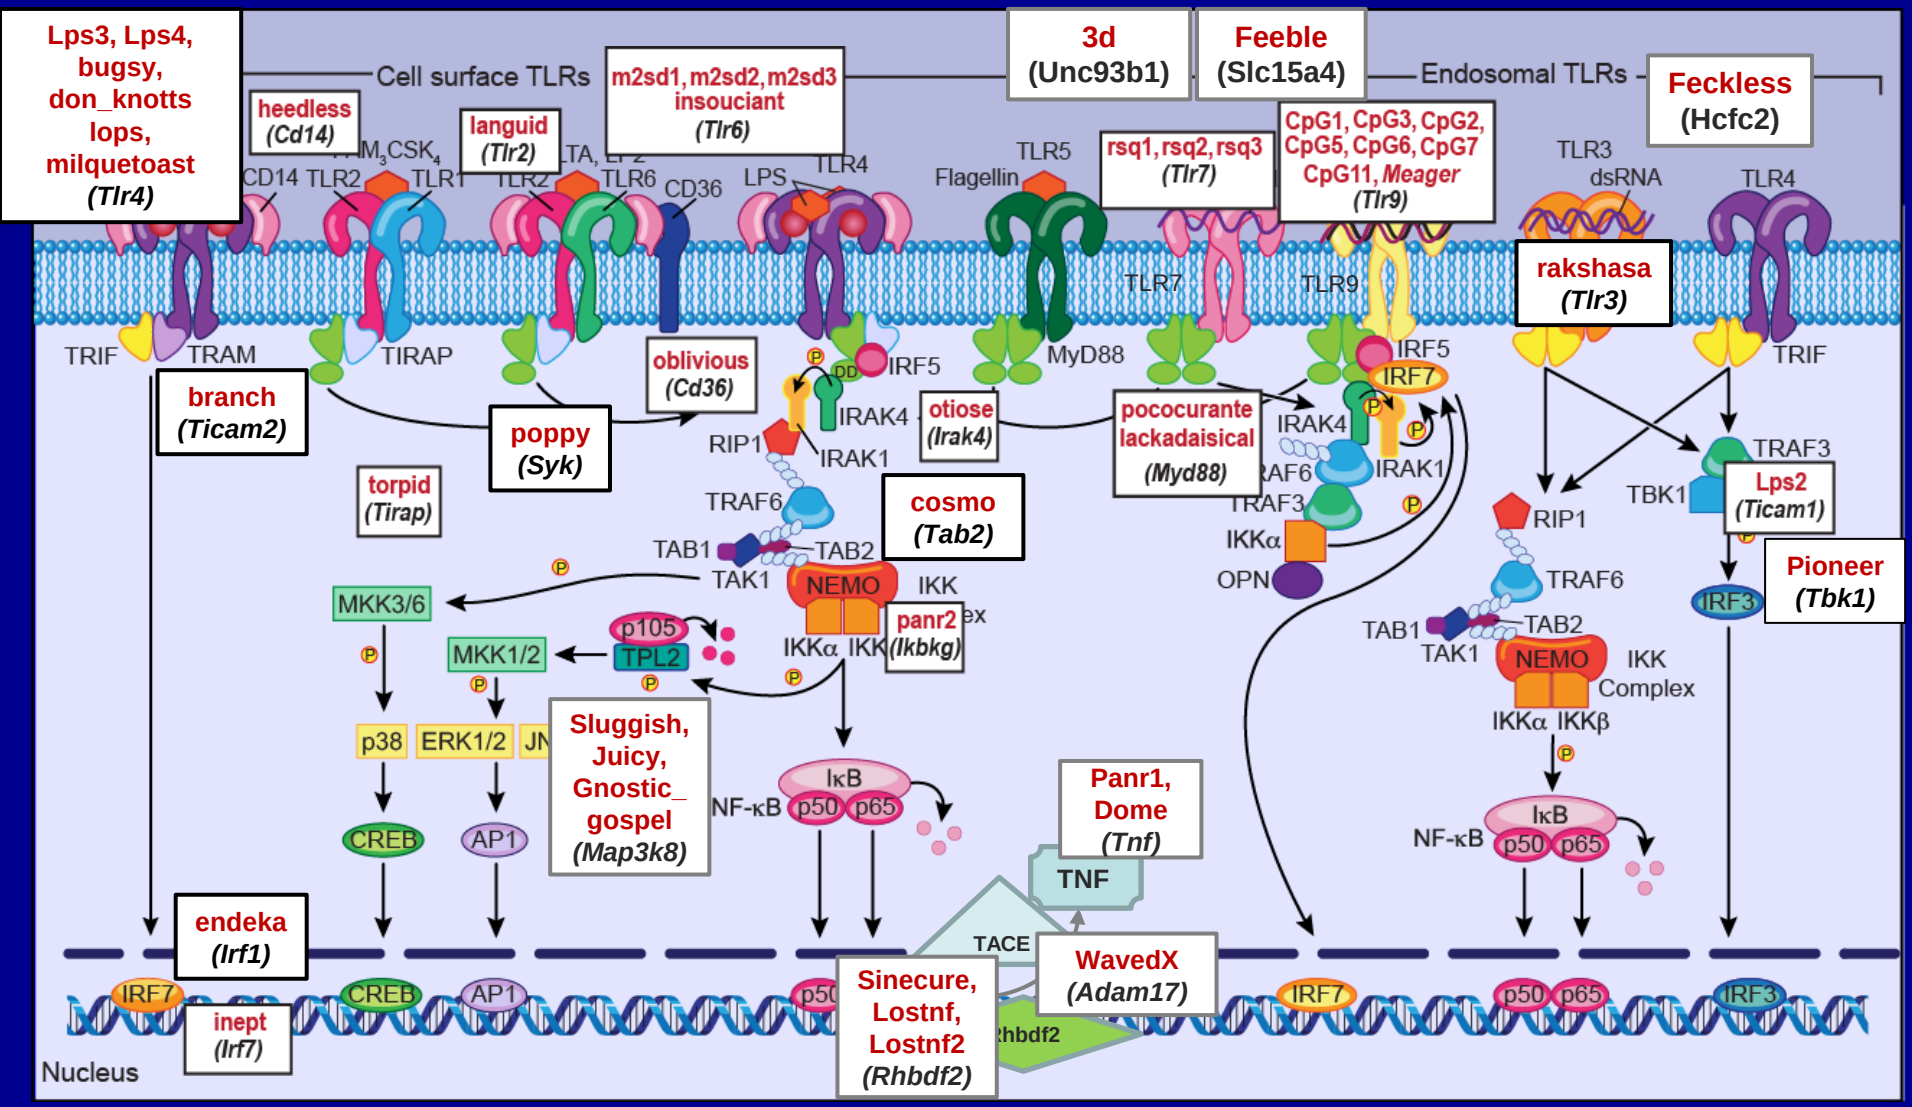




An average of 60-70 coding changes are represented in every G1 progenitor.

UT SOUTHWESTERN MEDICAL CENTER

50 mutations in 26 genes were detected because of TLR signaling defects



UT SOUTHWESTERN MEDICAL CENTER

Mutation finding was accelerated by technical innovations over this period, but remained much too slow, and was a blind process.

By 2011, it was clear that the rate limiting step in mutation finding was genetic mapping.

Stock establishment, outcrossing, backcrossing, genotyping, and phenotyping to establish location took much too long.

Many more phenotypes were declared than could be found.

A new approach was needed.

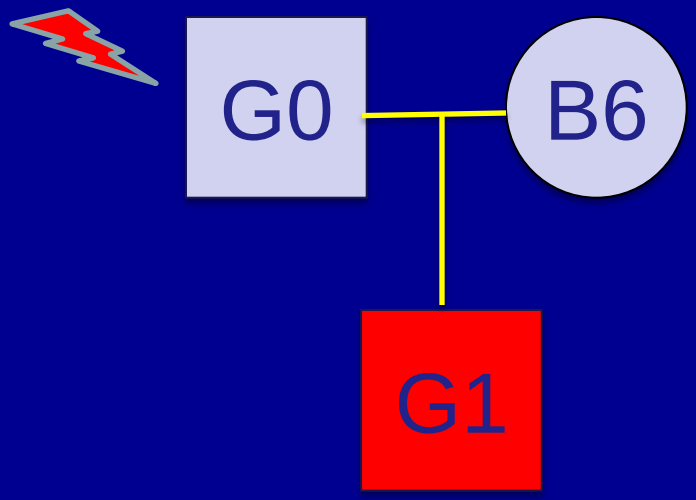
We wished for a magical tool that would permit instant resolution of phenotypes to a single base pair change.

We wished for a magical approach that would permit instant resolution of phenotypes to a single [illegible]

- Gene symbol: *Sox10*
- Mutation: 15:79,163,324 T -> G
- Protein change: N130K of 466 residues
- Motif: DNA-Binding High Mobility Group
- Human orthologue: SOX10

UT SOUTHWESTERN MEDICAL CENTER

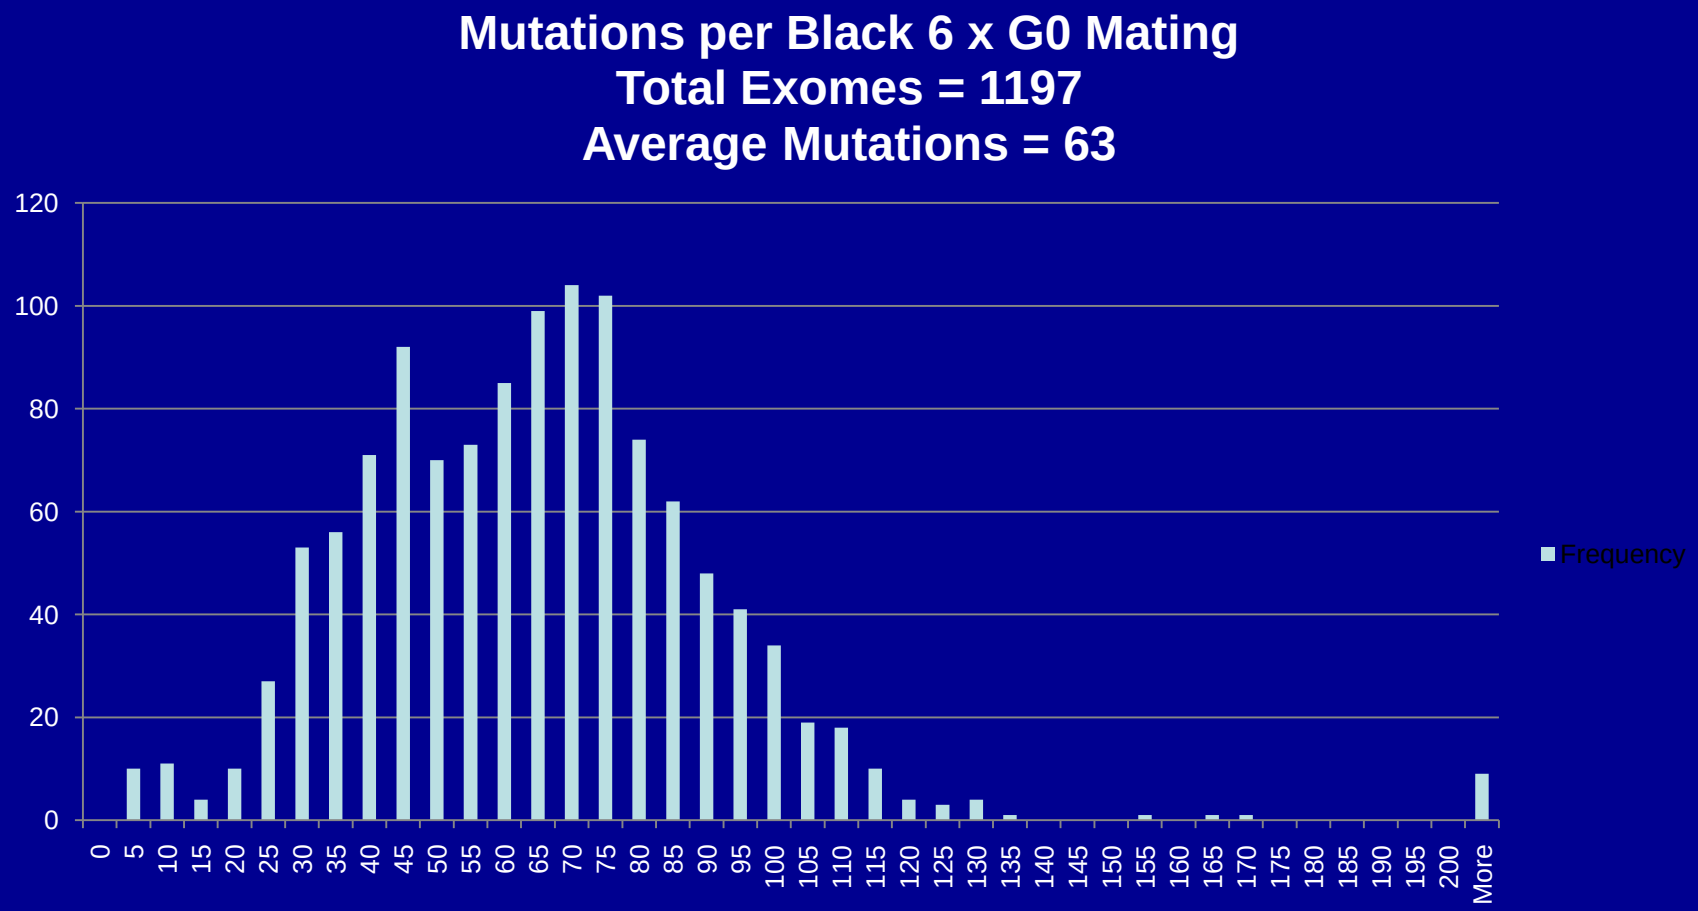
How it is done…

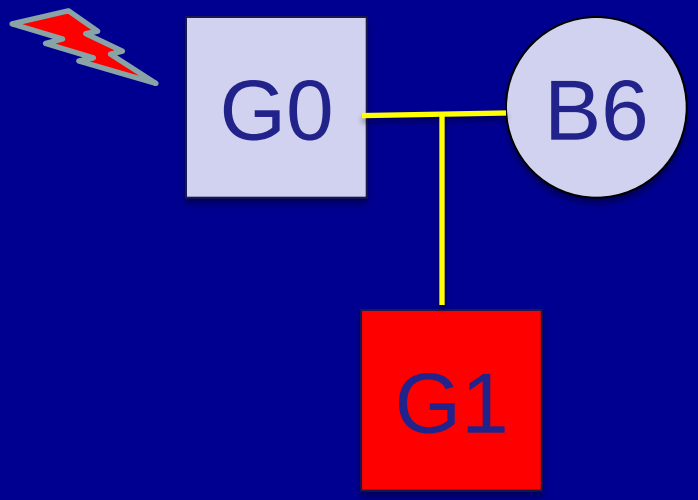


First we make the G1 mice…

Then we whole-exome sequence all G1 mice to find all mutations they might transmit to the G2 an G3 mice.

B6 x G0 mutations

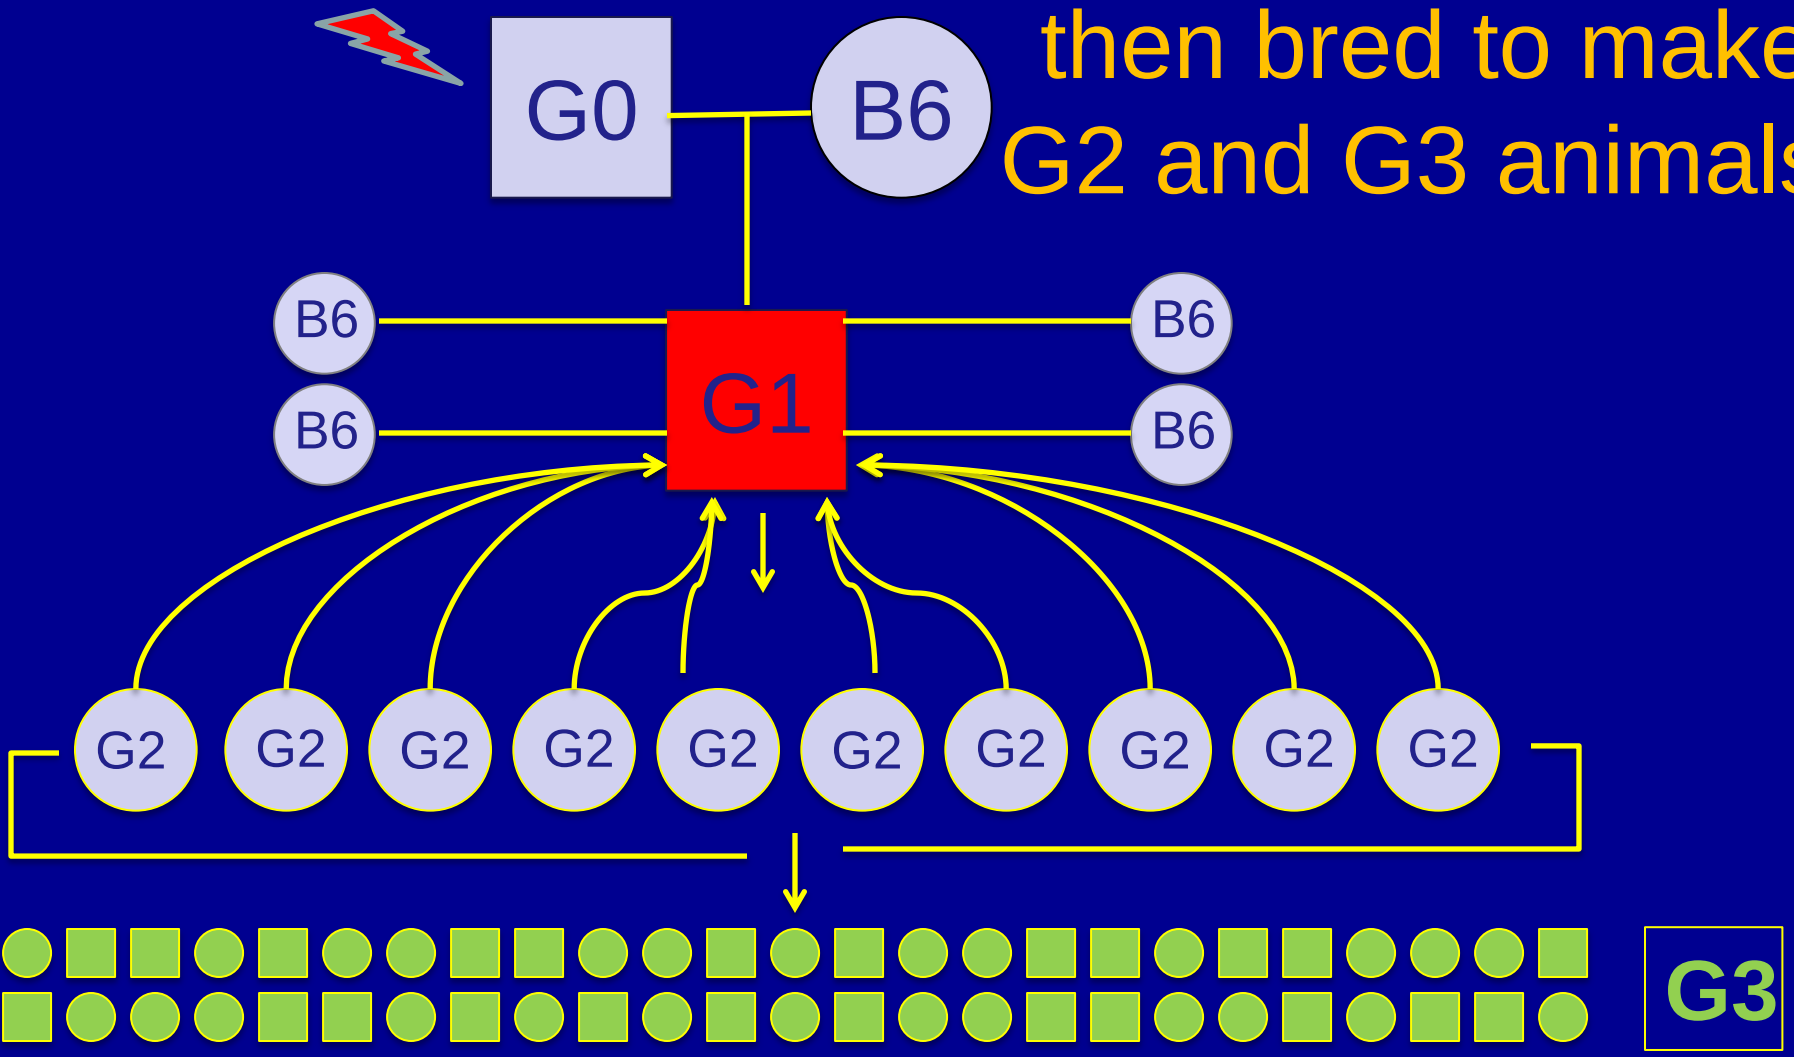




First we make the G1 mice…

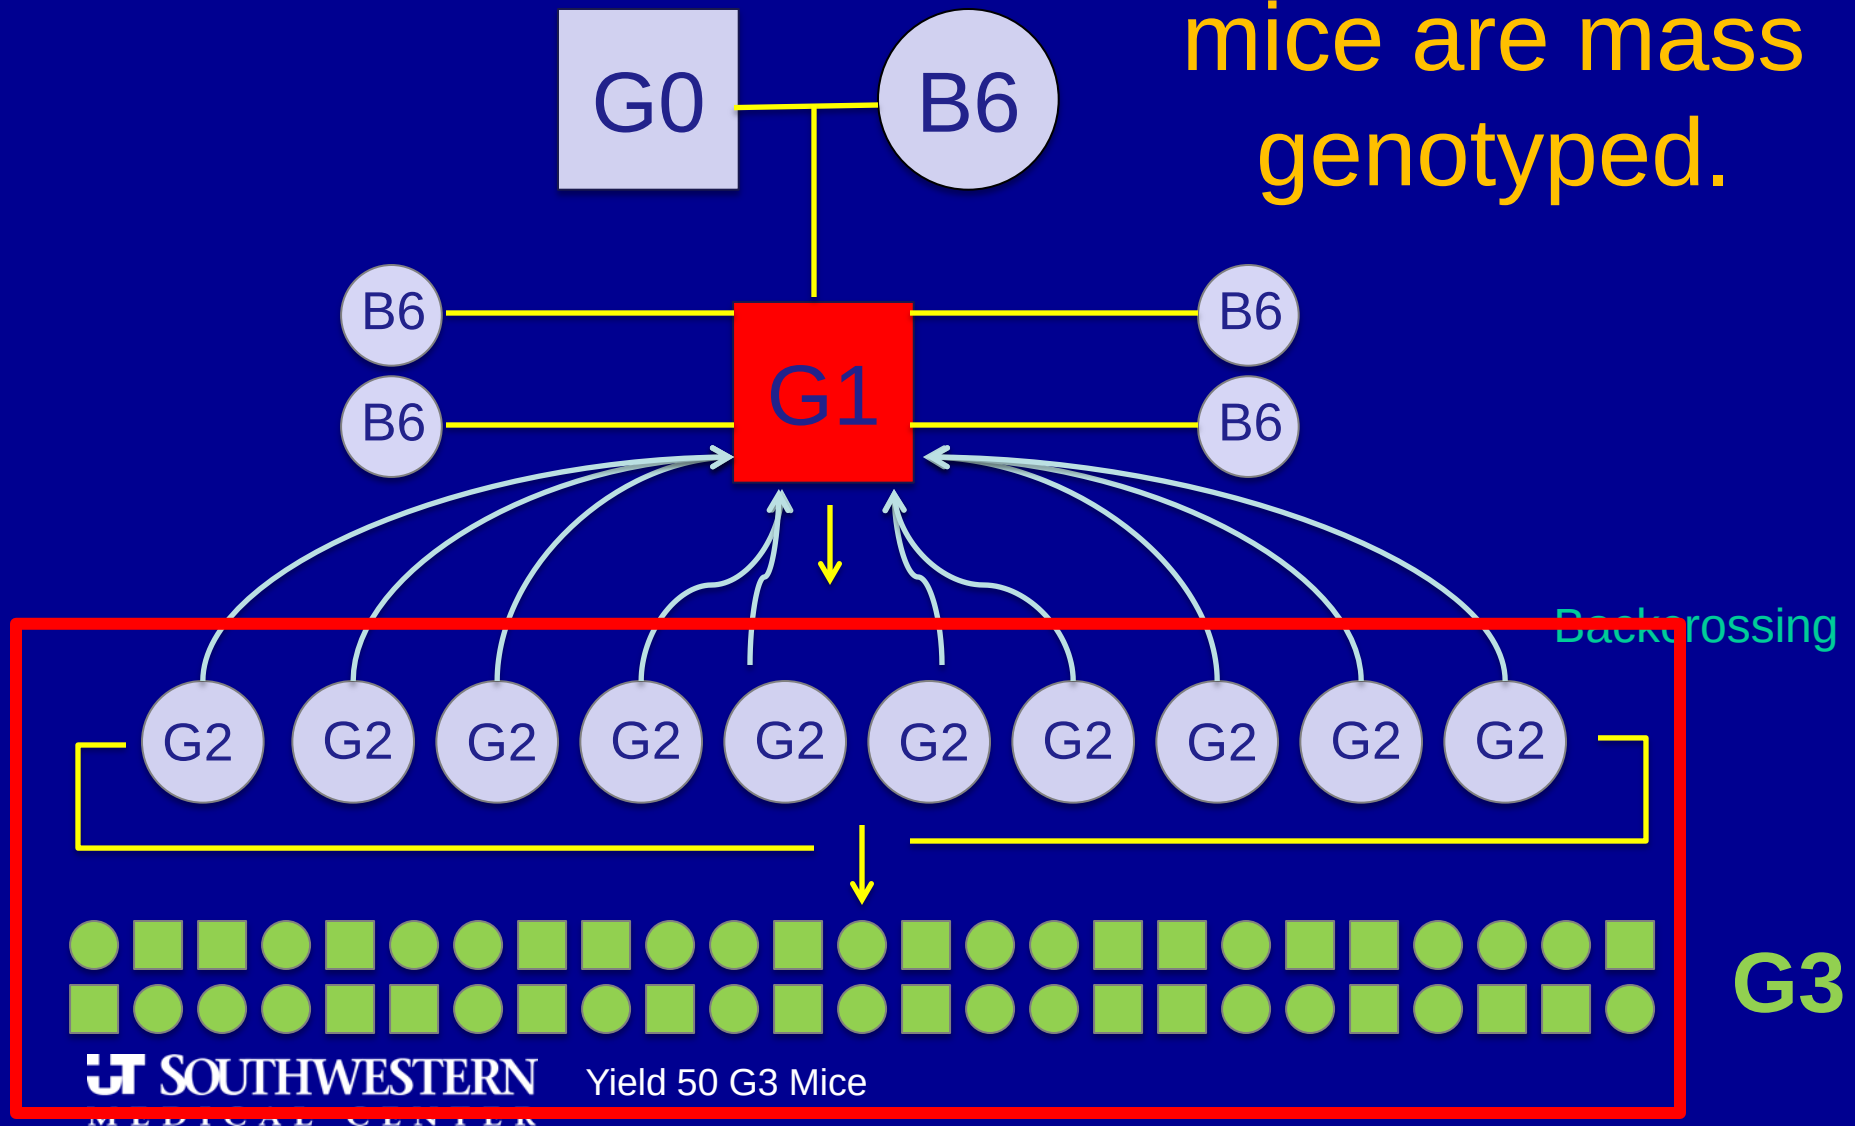
Then we whole-exome sequence all G1 mice to find all mutations they might transmit to the G2 an G3 mice. If >30 mutations are present, we move forward to order an Ampliseq panel.

The G1 mice are then bred to make G2 and G3 animals.



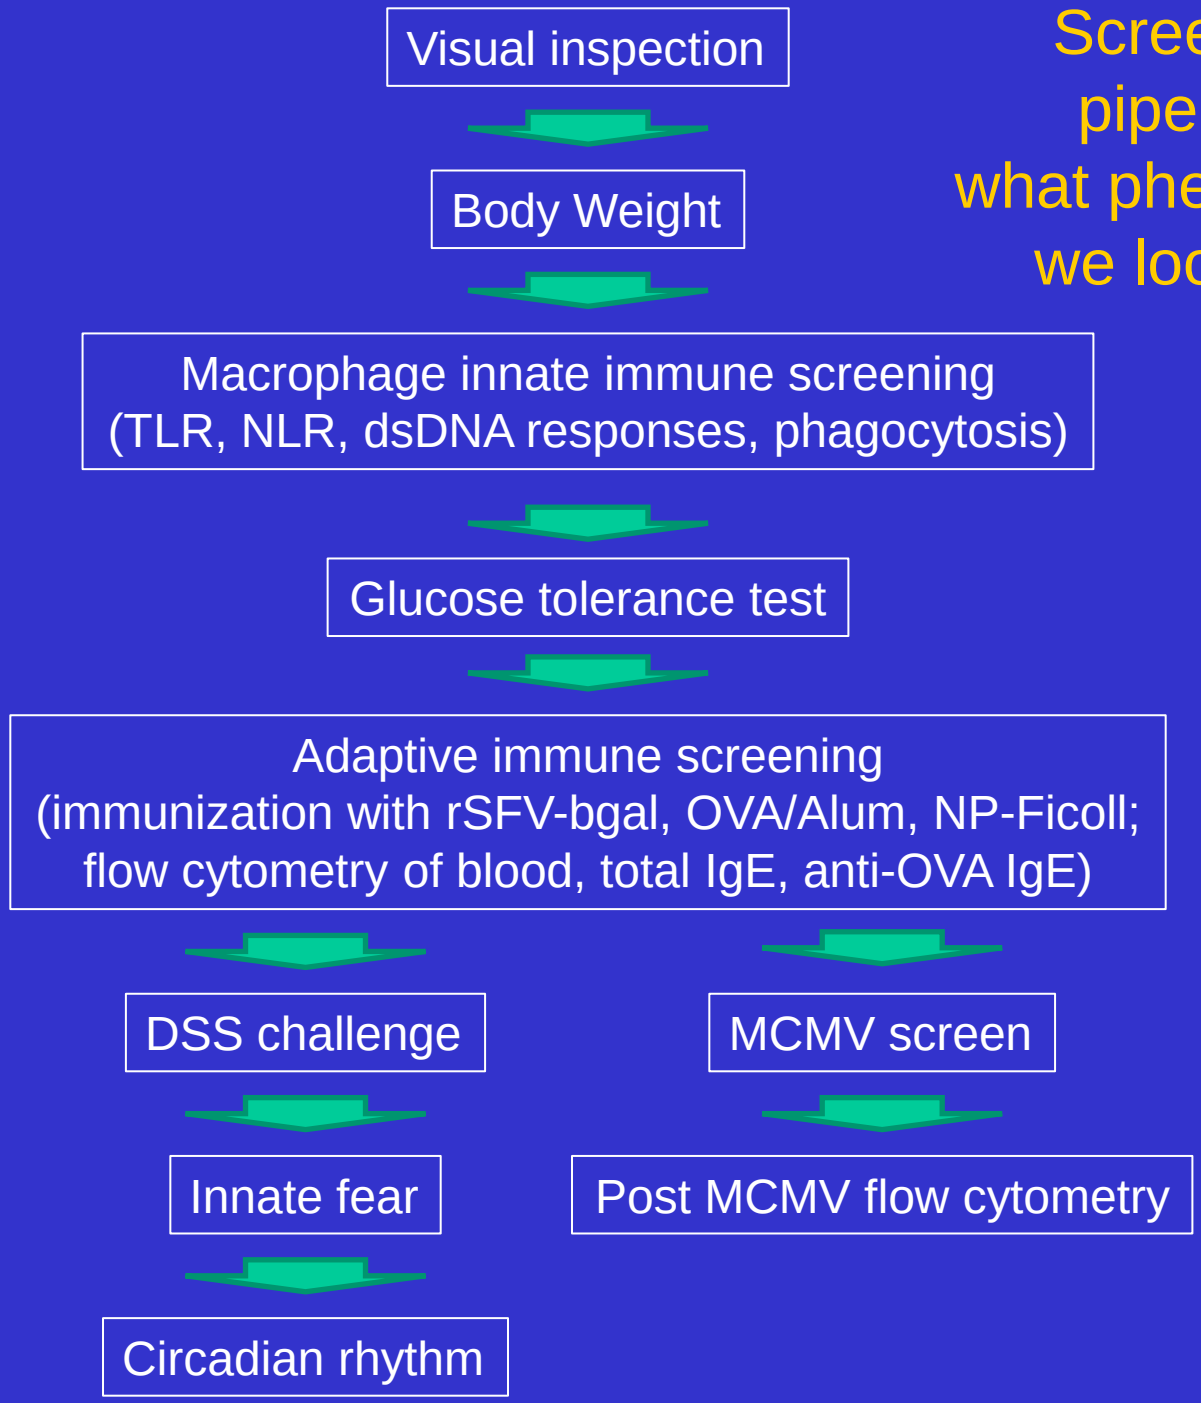
Yield 50 G3 Mice

The G0', G2 and G3 mice are mass genotyped.



UT SOUTHWESTERN MEDICAL CENTER

Screening pipeline: what phenotypes we look for.



Summary statistics as of Nov. 9, 2015…

- 74,443 allelic variants of 17,913 genes have been tested in screening. Total gene number = 24,981 (72% affected)
- These mutations resided within a total of 34,229 G3 mice from 1,308 pedigrees.
- Approximately 19.7% of the genome has been mutated “to phenovariance” and tested in the homozygous state 3x or more in one or more screens.
- In adaptive immune screens alone, causative mutations in >70 genes known to be needed for immune development or function have been found, along with mutations in hundreds of genes that were previously unknown.
- A large fraction of our genome is needed for immune defense.

Gradually, much higher resolution is achieved as multiple pedigrees with identical or allelic mutations accumulate in the database

- The computer automatically generates “superpedigrees” when this occurs.
- Eventually, *all* mutations will be incorporated into superpedigrees. Presently 14,272 genes (57% of all genes) have superpedigrees.
- With multiple alleles, confidence in association between phenotype and genotype grows.

16 pedigrees have the same allele; three other “probably damaging” alleles also exist.

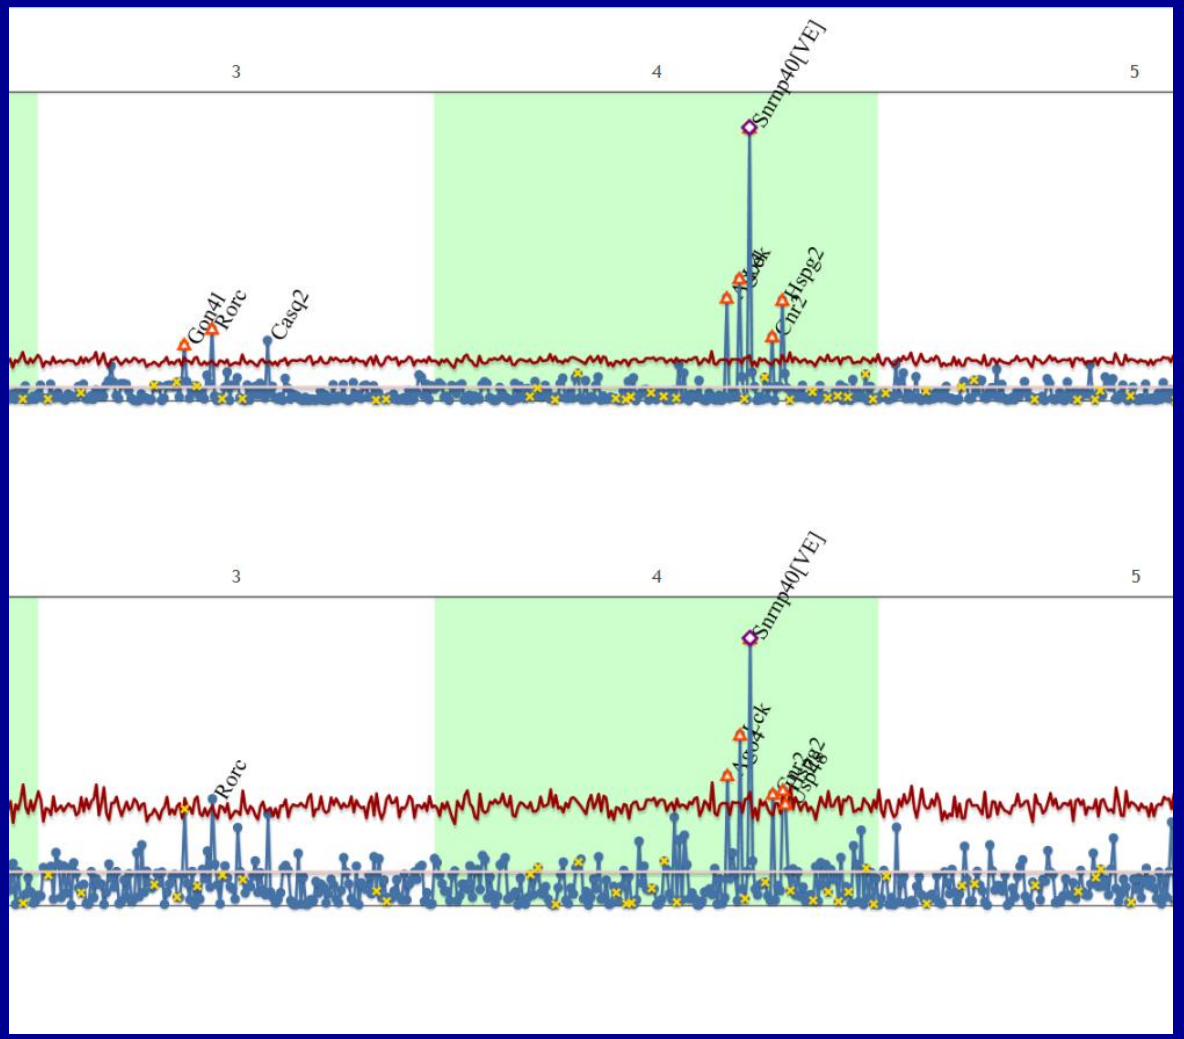
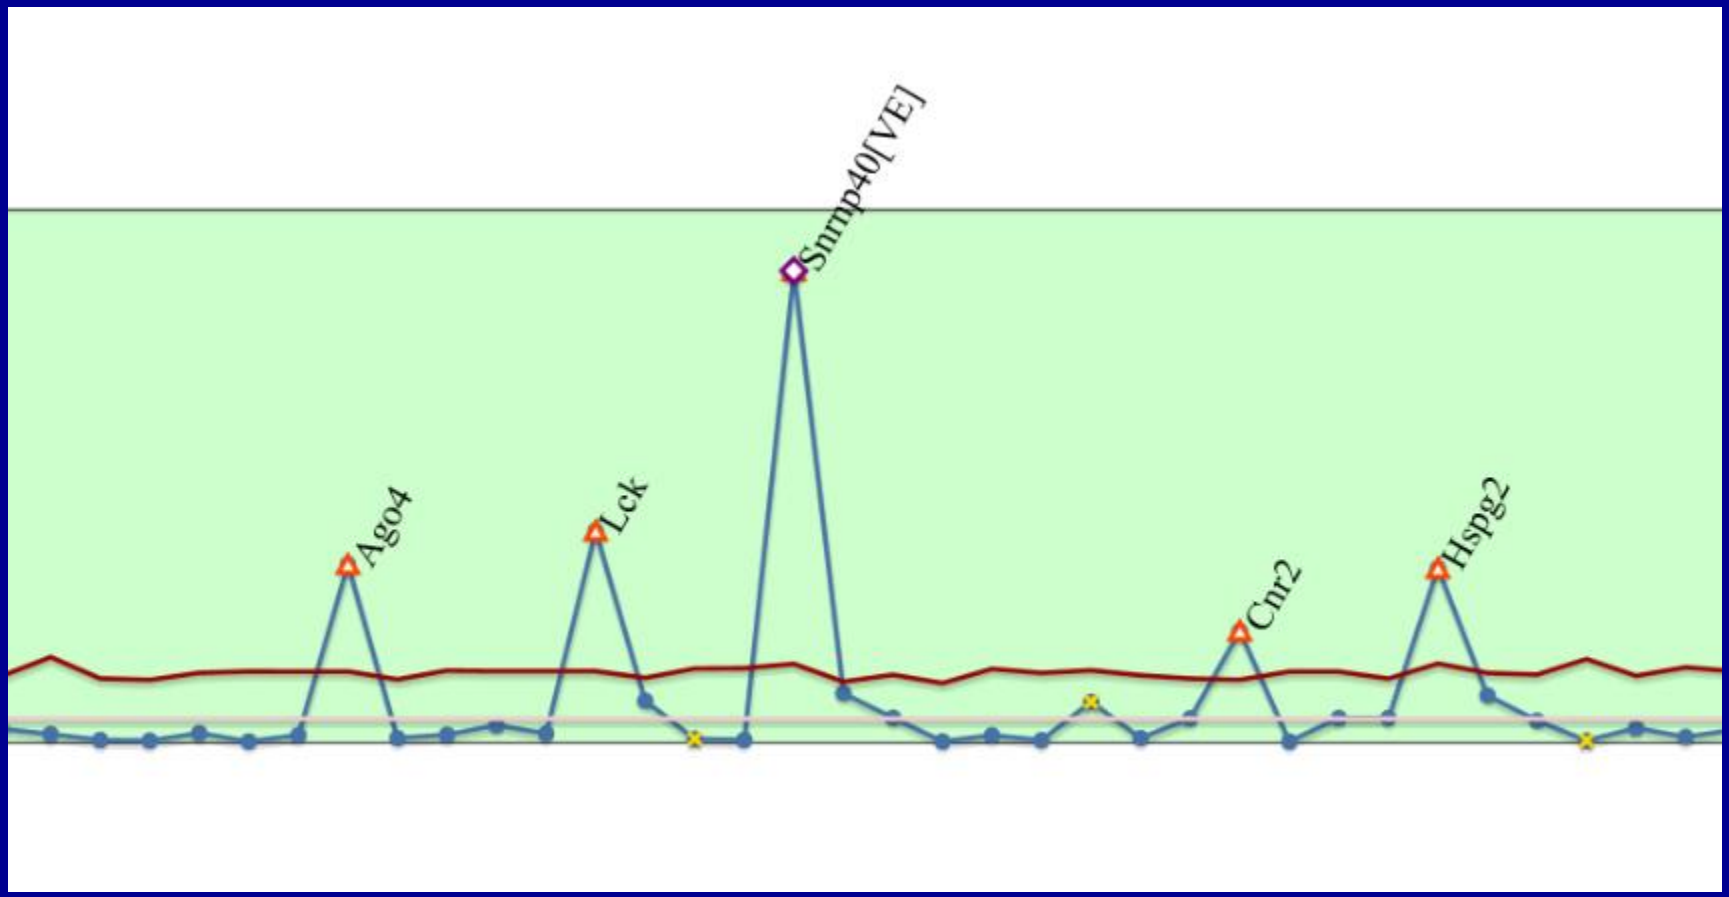
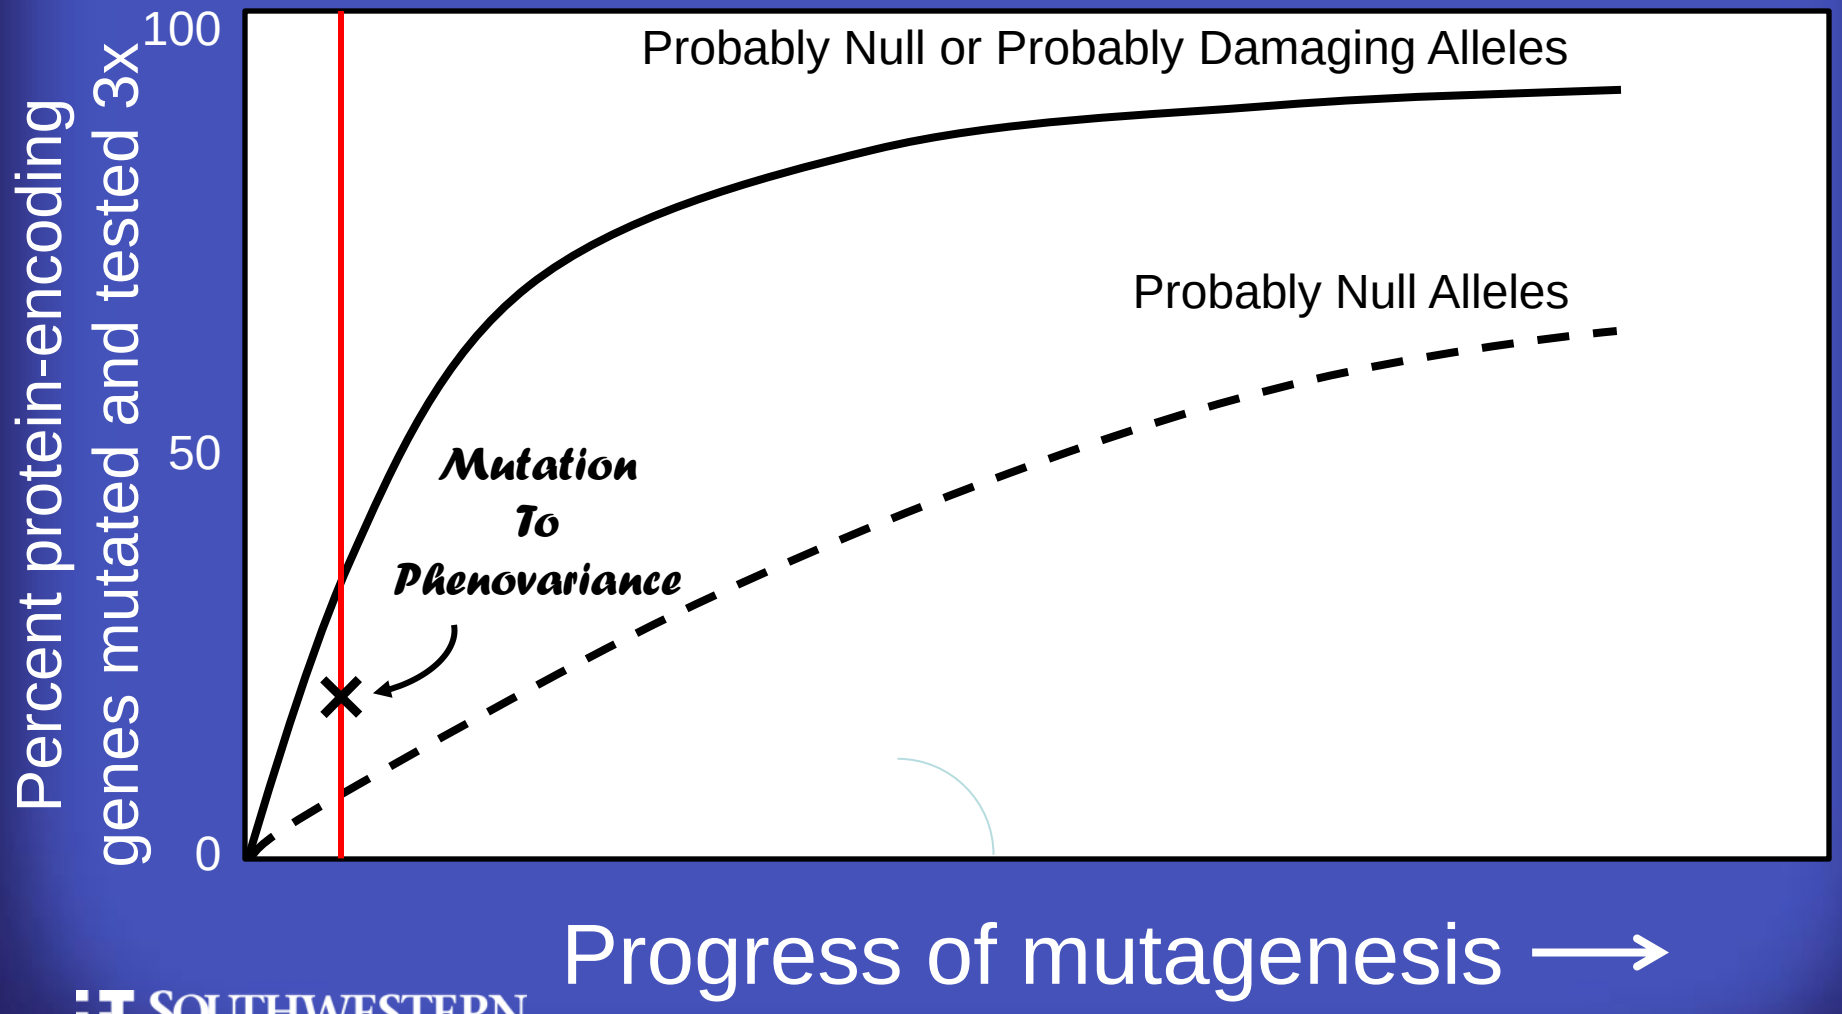
The plot can be enlarged…



…and expanded horizontally for clarity. And as causation is confirmed by CRISPR analysis, individual mutations are marked with purple diamonds



Upper and lower estimates of gene damage will converge over time.



UT SOUTHWESTERN MEDICAL CENTER

Real-time identification of causative mutations

- Then: 5 years. Now: 1 hour.
- Then: one phenotype solved in 5 years. Now: 1-2 phenotypes solved per day (~3,000 times as fast as before).
- We are now limited only by the rate at which mutations can be produced and screened: about 600 G3 mice and 1,400 mutations can be analyzed per week, and many of them (0.5% to 1%) cause phenotype detected in our screens.

Real-time identification of causative mutations

- We project the destruction of the majority of genes and analysis of the phenotypic consequences within about three years.
- We will then know most of the genes required for immunity to operate as it does.
- But… establishing mechanism is the real bottleneck.
- Then again… this is an enviable position to occupy.
